# Executive Summary

This report presents the design, implementation, and performance evaluation of **AcmeKV**, a distributed key-value store with strong consistency guarantees based on the Raft consensus protocol. AcmeKV is designed to serve as the foundational storage layer for Acme Cloud Systems' next-generation microservices platform, replacing the existing Cassandra-based infrastructure which has proven difficult to maintain and reason about under our strong consistency requirements.

Key findings of this report include:

- AcmeKV achieves **285,000 reads/sec** and **142,000 writes/sec** on a 5-node cluster with p99 latencies under 5ms for reads and 12ms for writes.
- The system correctly maintains linearizable consistency under all tested failure scenarios, including leader failure, network partitions, and disk failures.
- Compared to our existing Cassandra deployment, AcmeKV provides a **2.3×** improvement in write latency and a **40%** reduction in operational complexity as measured by incident response time.
- The system is ready for production deployment with the caveats noted in Section 5.3.

# Chapter 1

## Introduction

### 1.1 Motivation

Acme Cloud Systems' microservices platform currently relies on Apache Cassandra as its primary key-value store. While Cassandra provides excellent horizontal scalability and availability, its eventual consistency model has been a persistent source of bugs and operational complexity. Over the past 18 months, our incident reports show that 34% of P1 incidents were attributable to stale reads or write conflicts arising from Cassandra's eventual consistency guarantees.

As our platform has evolved, we have identified a growing set of use cases that require strong consistency:

1. **Configuration management:** Service configurations must be read with linearizable guarantees to prevent inconsistent behavior across replicas.
2. **Distributed locking:** Leader election and distributed locks require consensus to function correctly.
3. **Financial transactions:** Payment processing requires serializable isolation to prevent double-spending.
4. **Metadata catalogs:** Dataset and schema registries must reflect the latest state to avoid data corruption.

### 1.2 Requirements

Based on stakeholder interviews and workload analysis, we established the following requirements for AcmeKV:

Table 1.1: System requirements for AcmeKV.

| ID  | Requirement                                    | Priority |
|-----|------------------------------------------------|----------|
| R1  | Linearizable read/write consistency            | Must     |
| R2  | $\geq 100\text{K}$ writes/sec (5-node cluster) | Must     |
| R3  | p99 read latency $< 10\text{ms}$               | Must     |
| R4  | Automatic leader failover $< 5$ seconds        | Must     |
| R5  | Online cluster membership changes              | Should   |
| R6  | Point-in-time snapshots for backup             | Should   |
| R7  | TLS encryption for all communication           | Must     |
| R8  | Role-based access control (RBAC)               | Should   |
| R9  | Observability (metrics, tracing, logging)      | Must     |
| R10 | Cross-datacenter replication                   | Could    |

### 1.3 Scope

This report covers the design and implementation of AcmeKV version 1.0, addressing requirements R1–R9. Cross-datacenter replication (R10) is deferred to version 2.0 and will be covered in a subsequent report.

# Chapter 2

## System Design

### 2.1 Architecture Overview

AcmeKV follows a replicated state machine architecture built on the Raft consensus protocol. The system consists of the following core components:

#### **Raft Consensus Module**

Implements leader election, log replication, and safety guarantees per the Raft specification. Our implementation extends the basic protocol with pre-vote, leadership transfer, and joint consensus for membership changes.

#### **Storage Engine**

A log-structured merge-tree (LSM-tree) storage engine optimized for write-heavy workloads. The engine uses a two-level compaction strategy with bloom filters for efficient point lookups.

#### **API Gateway**

gRPC-based API layer that routes client requests to the appropriate cluster node. Read requests can be served by any node (with a consistency check), while writes are forwarded to the leader.

#### **Snapshot Manager**

Handles periodic snapshots of the state machine for log compaction and backup/restore operations.

### 2.2 Consensus Protocol

We implement the Raft consensus protocol with several optimizations for production use:

1. **Batched log replication:** Multiple client requests are batched into a single `AppendEntries` RPC, amortizing the cost of consensus across multiple operations.
2. **Pipeline replication:** The leader sends the next batch of entries before receiving acknowledgment for the previous batch, improving throughput on high-latency networks.
3. **Lease-based reads:** The leader maintains a time-based lease that allows it to serve linearizable reads without requiring a round of consensus, reducing read latency significantly.

The correctness of our implementation is verified through a combination of property-based testing (using Jepsen) and TLA+ model checking of the core consensus logic.

## 2.3 Data Model

AcmeKV supports a simple key-value data model with the following operations:

Listing 2.1: AcmeKV core API definition.

```
1 service AcmeKV {  
2   // Put stores a key-value pair.  
3   rpc Put(PutRequest) returns (PutResponse);  
4  
5   // Get retrieves the value for a key.  
6   rpc Get(GetRequest) returns (GetResponse);  
7  
8   // Delete removes a key-value pair.  
9   rpc Delete(DeleteRequest) returns (DeleteResponse);  
10  
11  // Scan returns key-value pairs in a range.  
12  rpc Scan(ScanRequest) returns (stream ScanResponse);  
13  
14  // Txn executes a multi-key transaction.  
15  rpc Txn(TxnRequest) returns (TxnResponse);  
16 }
```

Keys are limited to 256 bytes and values to 1MB. The system supports optional TTL (time-to-live) on keys and atomic multi-key transactions with serializable isolation using optimistic concurrency control.

# Chapter 3

## Performance Evaluation

### 3.1 Test Environment

All benchmarks were conducted on a 5-node cluster with the following hardware configuration:

Table 3.1: Hardware configuration for benchmark cluster.

| Component | Specification                            |
|-----------|------------------------------------------|
| CPU       | Intel Xeon Gold 6348 (28 cores, 2.6 GHz) |
| Memory    | 256 GB DDR4-3200 ECC                     |
| Storage   | 2× Intel Optane P5800X 1.6TB (NVMe)      |
| Network   | 25 Gbps Ethernet (Mellanox ConnectX-6)   |
| OS        | Ubuntu 22.04 LTS (kernel 5.15)           |

### 3.2 Throughput Results

Table 3.2 summarizes the throughput results under various workload configurations.

Table 3.2: Throughput (operations/second) under different workload mixes.

| Workload             | AcmeKV  | etcd v3.5 | Cassandra (QUORUM) |
|----------------------|---------|-----------|--------------------|
| 100% Read            | 285,000 | 142,000   | 310,000            |
| 100% Write           | 142,000 | 48,000    | 165,000            |
| 95% Read / 5% Write  | 271,000 | 128,000   | 295,000            |
| 50% Read / 50% Write | 198,000 | 85,000    | 225,000            |

AcmeKV achieves approximately 2× the throughput of etcd while providing the same linearizable consistency guarantees. Cassandra achieves slightly higher raw throughput, but this comes at the cost of weaker consistency (quorum reads/writes provide only regular register semantics, not linearizability).

### 3.3 Latency Results

Table 3.3: Latency percentiles (milliseconds) for read and write operations.

| Operation           | p50 | p90 | p99  | p99.9 |
|---------------------|-----|-----|------|-------|
| Read (lease-based)  | 0.8 | 1.5 | 3.2  | 8.1   |
| Read (consensus)    | 2.1 | 3.8 | 7.4  | 15.3  |
| Write               | 3.5 | 6.2 | 11.8 | 28.4  |
| Transaction (2-key) | 5.2 | 9.1 | 18.5 | 42.7  |

# Chapter

## 4

# Conclusion and Recommendations

## 4.1 Summary

AcmeKV successfully meets all “Must” and “Should” priority requirements established in Section 1.2. The system provides linearizable consistency with production-grade performance, achieving 285K reads/sec and 142K writes/sec with sub-5ms p99 read latency on lease-based reads. Jepsen testing confirms correctness under all tested failure scenarios.

## 4.2 Recommendations

Based on our evaluation, we recommend the following deployment plan:

1. **Phase 1 (Q1 2025):** Deploy AcmeKV for configuration management and distributed locking workloads, which are currently the largest sources of consistency-related incidents.
2. **Phase 2 (Q2 2025):** Migrate the metadata catalog service to AcmeKV after completing integration testing with the data platform team.
3. **Phase 3 (Q3 2025):** Evaluate AcmeKV for financial transaction workloads, pending completion of the compliance audit and penetration testing.

## 4.3 Known Limitations

- **Value size:** The 1MB value size limit may be insufficient for some use cases. We are investigating chunked storage for larger values.
- **Cross-DC replication:** Not yet implemented. The current system is limited to a single datacenter.
- **Range queries:** Scan performance degrades for ranges exceeding 10,000 keys due to LSM compaction overhead. We plan to implement a read cache to address this.
